## Repeated Games

## Long Run versus Short Run Player

a fixed simultaneous move stage game

Player 1 is long-run with discount factor $\delta$
actions $a^{1} \in A^{1}$ a finite set
utility $u^{1}\left(a^{1}, a^{2}\right)$

Player 2 is short-run with discount factor 0
actions $a^{2} \in A^{2}$ a finite set
utility $u^{2}\left(a^{1}, a^{2}\right)$

## What it is about

the "short-run" player may be viewed as a kind of "representative" of many "small" long-run players

- the "usual" case in macroeconomic/political economy models
- the "long run" player is the government
- the "short-run" player is a representative individual

## Example 1: Peasant-Dictator

## Example 2: Backus-Driffil

|  | Low | High |
| :--- | :--- | :--- |
| Low | High | 0,0 |
| $1,-1$ | $-2,-1$ |  |
|  |  |  |

Inflation Game: LR=government, SR=consumers consumer preferences are whether or not they guess right

|  | Low | High |
| :--- | :--- | :--- |
| Low | 0,0 | $0,-1$ |
| High | $-1,-1$ | $-1,0$ |

with a hard-nosed government

## Repeated Game

history $h_{t}=\left(a_{1}, a_{2}, \ldots, a_{t}\right)$
null history $h_{0}$
behavior strategies $\alpha_{t}^{i}=\sigma^{i}\left(h_{t-1}\right)$
long run player preferences
average discounted utility
$(1-\delta) \sum_{t=1}^{T} \delta^{t-1} u^{i}\left(a_{t}\right)$
note that average present value of 1 unit of utility per period is 1

## Equilibrium

Nash equilibrium: usual definition - cannot gain by deviating
Subgame perfect equilibrium: usual definition, Nash after each history
Observation: the repeated static equilibrium of the stage game is a subgame perfect equilibrium of the finitely or infinitely repeated game

- strategies: play the static equilibrium strategy no matter what

## "perfect equilibrium with public randomization"

may use a public randomization device at the beginning of each period to pick an equilibrium
key implication: set of equilibrium payoffs is convex

## Example: Peasant-Dictator

normal form: unique Nash equilibrium high, eat

|  | eat | grow |
| :--- | :--- | :--- |
| low | $0^{*}, 1$ | $1,2^{*}$ |
| $0^{*}, 1^{*}$ | $3^{*}, 0$ |  |

## Static Benchmarks

payoff at static Nash equilibrium to LR player: 0
precommitment or Stackelberg equilibrium
precommit to low get 1
mixed precommitment to $50-50$ get 2
minmax payoff to LR player: 0

## Payoff Space

utility to long-run player
mixed precommitment/Stackelberg $=2$
best dynamic equilibrium = ?
pure precommitment/Stackelberg = 1
Set of dynamic equilibria
static Nash $=0$
worst dynamic equilibrium $=$ ?
$-\operatorname{minmax}=0$

## Repeated Peasant-Dictator

finitely repeated game
final period: high, eat, so same in every period
Do you believe this??

- Infinitely repeated game
begin by low, grow
if low, grow has been played in every previous period then play low, grow
otherwise play high, eat (reversion to static Nash)
claim: this is subgame perfect

## When is this an equilibrium?

clearly a Nash equilibrium following a history with high or eat SR play is clearly optimal
for LR player
may high and get $(1-\delta) 3+\delta 0$
or low and get 1
so condition for subgame perfection
$(1-\delta) 3 \leq 1, \delta \geq 2 / 3$

## Equilibrium Utility

equilibrium utility for LR

## General Deterministic Case

## Fudenberg, Kreps and Maskin

$+\max u^{1}(a)$
mixed precommitment/Stackelberg
$\bar{v}^{1}$ best dynamic equilibrium
pure precommitment/Stackelberg
Set of dynamic equilibria
static Nash
$\underline{v}^{1}$ worst dynamic equilibrium
minmax
$-\min u^{1}(a)$

## Characterization of Equilibrium Payoff

$\alpha=\left(\alpha^{1}, \alpha^{2}\right)$ where $\alpha^{2}$ is a b.r. to $\alpha^{1}$
$\alpha$ represent play in the first period of the equilibrium $w^{1}\left(a^{1}\right)$ represents the equilibrium payoff beginning in the next period

$$
\begin{aligned}
& v^{1} \geq(1-\delta) u^{1}\left(a^{1}, \alpha^{2}\right)+\delta w^{1}\left(a^{1}\right) \\
& v^{1}=(1-\delta) u^{1}\left(a^{1}, \alpha^{2}\right)+\delta w^{1}\left(a^{1}\right), \alpha^{1}\left(a^{1}\right)>0 \\
& \underline{v}^{1} \leq w^{1}\left(a^{1}\right) \leq \bar{v}^{1}
\end{aligned}
$$

## Simplified Approach

impose stronger constraint using $n$ static Nash payoff
for best equilibrium $n \leq w^{1}\left(a^{1}\right) \leq \bar{v}^{1}$
for worst equilibrium $\underline{v}^{1} \leq w^{1}\left(a^{1}\right) \leq n$
avoids problem of best depending on worst
remark: if we have static Nash = minmax then no computation is neede for the worst, and the best calculation is exact.

## max problem

fix $\alpha=\left(\alpha^{1}, \alpha^{2}\right)$ where $\alpha^{2}$ is a b.r. to $\alpha^{1}$
$\bar{v}^{1} \geq(1-\delta) u^{1}\left(a^{1}, \alpha^{2}\right)+\delta w^{1}\left(a^{1}\right)$
$\bar{v}^{1}=(1-\delta) u^{1}\left(a^{1}, \alpha^{2}\right)+\delta w^{1}\left(a^{1}\right), \alpha^{1}\left(a^{1}\right)>0$
$n^{1} \leq w^{1}\left(a^{1}\right) \leq \bar{v}^{1}$
how big can $w^{1}\left(a^{1}\right)$ be in = case?

Biggest when $u^{1}\left(a^{1}, \alpha^{2}\right)$ is smallest, in which case
$w^{1}\left(a^{1}\right)=\bar{v}^{1}$
$\bar{v}^{1}=(1-\delta) u^{1}\left(a^{1}, \alpha^{2}\right)+\delta \bar{v}^{1}$

## Summary

conclusion for fixed $\alpha$
$\min _{a^{1} \mid \alpha\left(a^{1}\right)>0} u^{1}\left(a^{1}, \alpha^{2}\right)$
i.e. worst in support
$\bar{v}^{1}=\max _{\alpha^{2} \in E R^{2}\left(a^{1}\right)} \min _{a^{1} \mid \alpha\left(a^{1}\right)>0} u^{1}\left(a^{1}, \alpha^{2}\right)$
observe:
mixed precommitment $\geq \bar{v}^{1} \geq$ pure precommitment

## Peasant-Dictator Example

|  | eat | grow |
| :--- | :--- | :--- |
| low | $0^{*}, 1$ | $1,2^{*}$ |
| high | $0^{*}, 1^{*}$ | $3^{*}, 0$ |

| $p$ (low) | BR |  |
| :--- | :--- | :--- |
| 1 | grow | 1 |
| $1 / 2<p<1$ | grow | 1 |
| $p=1 / 2$ | any mixture | $\leq 1$ (low) |
| $0<p<1 / 2$ | eat | 0 |
| $p=0$ | eat | 0 |

## Check the constraints

$$
\begin{aligned}
& w^{1}\left(a^{1}\right)=\frac{\bar{v}^{1}-(1-\delta) u^{1}\left(a^{1}, \alpha^{2}\right)}{\delta} \geq n^{1} \\
& \text { as } \delta \rightarrow 1 \text { then } w^{1}\left(a^{1}\right) \rightarrow \bar{v}^{1} \geq n^{1}
\end{aligned}
$$

## min problem

fix $\alpha=\left(\alpha^{1}, \alpha^{2}\right)$ where $\alpha^{2}$ is a b.r. to $\alpha^{1}$
$\underline{v}^{1} \geq(1-\delta) u^{1}\left(a^{1}, \alpha^{2}\right)+\delta w^{1}\left(a^{1}\right)$
$\underline{v}^{1} \leq w^{1}\left(a^{1}\right) \leq n^{1}$

Biggest $u^{1}\left(a^{1}, \alpha^{2}\right)$ must have smallest $w^{1}\left(a^{1}\right)=\underline{v}^{1}$
$\underline{v}^{1}=(1-\delta) u^{1}\left(a^{1}, \alpha^{2}\right)+\delta \underline{v}^{1}$
conclusion
$\underline{v}^{1}=\max u^{1}\left(a^{1}, \alpha^{2}\right)$
or
$\underline{v}^{1}=\min _{\alpha^{2} \in B R^{2}\left(\alpha^{1}\right)} \max u^{1}\left(a^{1}, \alpha^{2}\right)$, that is, constrained minmax

## Worst Equilibrium Example

|  | L | M | R |
| :--- | :--- | :--- | :--- |
| $U$ | $0,-3$ | 1,2 | 0,3 |
| $D$ | $0,3^{*}$ | 2,2 | 0,0 |

static Nash gives 0
minmax gives 0
worst payoff in fact is 0
pure precommitment also 0

## mixed precommitment

$p$ is probability of up
to get more than 0 must get SR to play M
$-3 p+(1-p) 3 \leq 2$ and $3 p \leq 2$
first one
$-3 p+(1-p) 3 \leq 2 \quad 3 p \leq 2$
$-3 p-3 p \leq-1 \quad p \leq 2 / 3$
$p \geq 1 / 6$
want to play D so take $p=1 / 6$
get $1 / 6+10 / 6=11 / 6$

## Utility to long-run player

$+\max u^{1}(a)=2$
mixed precommitment/Stackelberg=11/16
$\bar{v}^{1}$ best dynamic equilibrium=1
pure precommitment/Stackelberg=0
Set of dynamic equilibria
static Nash=0
$v^{1}$ worst dynamic equilibrium $=0$
minmax=0
$\min u^{1}(a)=0$

## calculation of best dynamic equilibrium payoff

$p$ is probability of up

| $p$ | BR ${ }^{2}$ | worst in support |
| :--- | :--- | :--- |
| $<1 / 6$ | L | 0 |
| $1 / 6<p<5 / 6$ | M | 1 |
| $p>5 / 6$ | R | 0 |

so best dynamic payoff is 1
