# Long Run versus Short Run Player

*a fixed simultaneous move stage game*

Player 1 is long-run with discount factor  $\delta$

actions  $a^1 \in A^1$  a finite set

utility  $u^1(a^1, a^2)$

Player 2 is short-run with discount factor 0

actions  $a^2 \in A^2$  a finite set

utility  $u^2(a^1, a^2)$

the “short-run” player may be viewed as a kind of “representative” of many “small” long-run players

- ◆ the “usual” case in macroeconomic/political economy models
- ◆ the “long run” player is the government
- ◆ the “short-run” player is a representative individual

*Example 1: Peasant-Dictator*

*Example 2: Backus-Driffil*

|      | Low  | High  |
|------|------|-------|
| Low  | 0,0  | -2,-1 |
| High | 1,-1 | -1,0  |

Inflation Game: LR=government, SR=consumers

consumer preferences are whether or not they guess right

|      | Low   | High |
|------|-------|------|
| Low  | 0,0   | 0,-1 |
| High | -1,-1 | -1,0 |

with a hard-nosed government

## *Repeated Game*

history  $h_t = (a_1, a_2, \dots, a_t)$

null history  $h_0$

behavior strategies  $\alpha_t^i = \sigma^i(h_{t-1})$

long run player preferences

average discounted utility

$$(1 - \delta) \sum_{t=1}^T \delta^{t-1} u^i(a_t)$$

note that average present value of 1 unit of utility per period is 1

## *Equilibrium*

Nash equilibrium: usual definition – cannot gain by deviating

Subgame perfect equilibrium: usual definition, Nash after each history

Observation: the repeated static equilibrium of the stage game is a subgame perfect equilibrium of the finitely or infinitely repeated game

◆ strategies: play the static equilibrium strategy no matter what

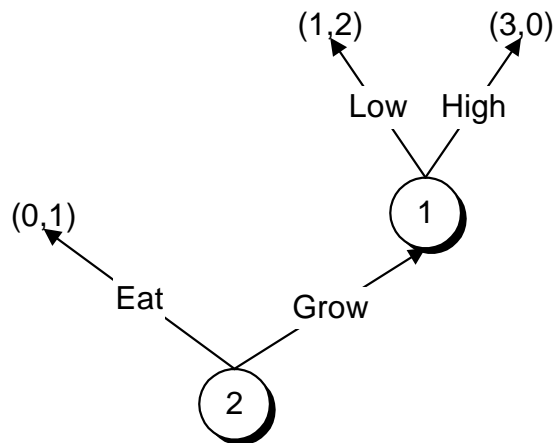

*“perfect equilibrium with public randomization”*

may use a public randomization device at the beginning of each period to pick an equilibrium

key implication: set of equilibrium payoffs is convex

## Example: Peasant-Dictator

normal form: unique Nash equilibrium **high, eat**

|      | eat   | grow |
|------|-------|------|
| low  | 0*,1  | 1,2* |
| high | 0*,1* | 3*,0 |

payoff at static Nash equilibrium to LR player: 0

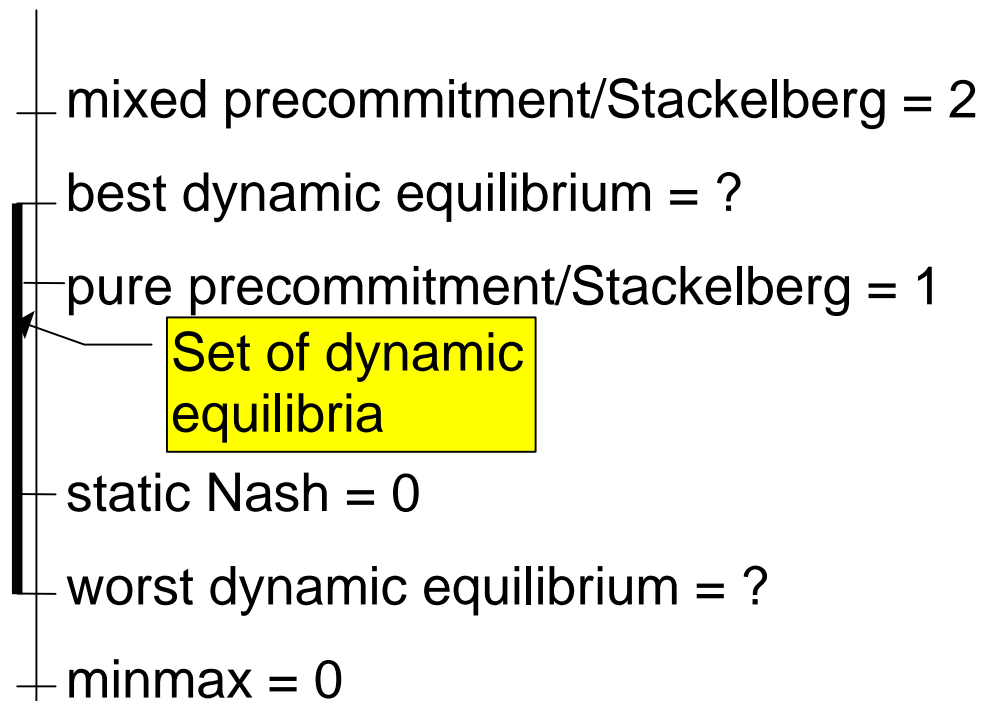

precommitment or Stackelberg equilibrium

precommit to low get 1

mixed precommitment to 50-50 get 2

minmax payoff to LR player: 0

utility to long-run player

## *Repeated Peasant-Dictator*

finitely repeated game

final period: high, eat, so same in every period

Do you believe this??

## *Infinitely repeated game*

begin by low, grow

if low, grow has been played in every previous period then play low, grow

otherwise play high, eat (reversion to static Nash)

claim: this is subgame perfect

clearly a Nash equilibrium following a history with high or eat  
SR play is clearly optimal

for LR player

may high and get

or low and get 1

so condition for subgame perfection

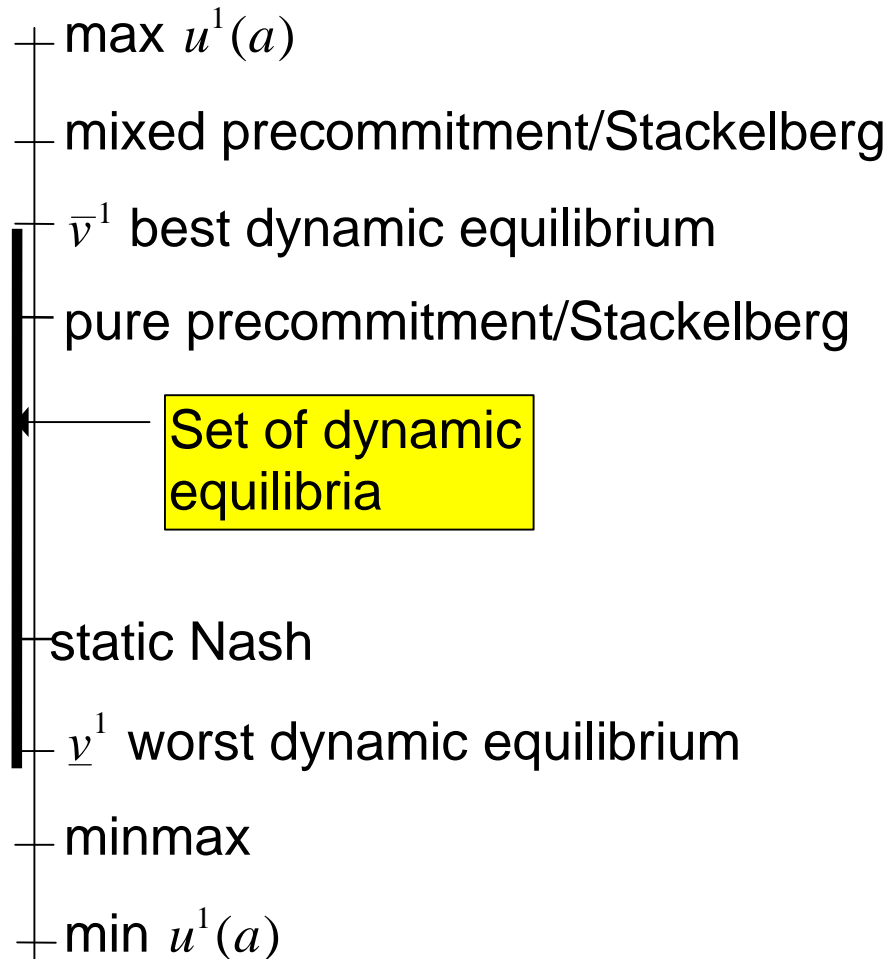

$$(1 - \delta)3 \leq 1$$

$$\delta \geq 2/3$$

equilibrium utility for LR

## General Deterministic Case (Fudenberg, Kreps and Maskin)

### *Characterization of Equilibrium Payoff*

$\alpha = (\alpha^1, \alpha^2)$  where  $\alpha^2$  is a b.r. to  $\alpha^1$

$\alpha$  represent play in the first period of the equilibrium

$w^1(a^1)$  represents the equilibrium payoff beginning in the next period

$$v^1 \geq (1 - \delta)u^1(a^1, \alpha^2) + \delta w^1(a^1)$$

$$v^1 = (1 - \delta)u^1(a^1, \alpha^2) + \delta w^1(a^1), \alpha^1(a^1) > 0$$

$$\underline{v}^1 \leq w^1(a^1) \leq \bar{v}^1$$

strategy: impose stronger constraint using  $n$  static Nash payoff

$$\text{for best equilibrium } n \leq w^1(a^1) \leq \bar{v}^1$$

$$\text{for worst equilibrium } \underline{v}^1 \leq w^1(a^1) \leq n$$

avoids problem of best depending on worst

remark: if we have static Nash = minmax then no computation is needed for the worst, and the best calculation is exact.

max problem

fix  $\alpha = (\alpha^1, \alpha^2)$  where  $\alpha^2$  is a b.r. to  $\alpha^1$

$$\bar{v}^1 \geq (1 - \delta)u^1(a^1, \alpha^2) + \delta w^1(a^1)$$

$$\bar{v}^1 = (1 - \delta)u^1(a^1, \alpha^2) + \delta w^1(a^1), \alpha^1(a^1) > 0$$

$$n^1 \leq w^1(a^1) \leq \bar{v}^1$$

how big can  $w^1(a^1)$  be in = case?

Biggest when  $u^1(a^1, \alpha^1)$  is smallest, in which case

$$w^1(a^1) = \bar{v}^1$$

$$\bar{v}^1 = (1 - \delta)u^1(a^1, \alpha^2) + \delta \bar{v}^1$$

conclusion for fixed  $\alpha$

$$\min_{a^1 | \alpha(a^1) > 0} u^1(a^1, \alpha^2)$$

i.e. worst in support

$$\bar{v}^1 = \max_{\alpha^2 \in BR^2(\alpha^1)} \min_{a^1 | \alpha(a^1) > 0} u^1(a^1, \alpha^2)$$

observe:

mixed precommitment  $\geq \bar{v}^1 \geq$  pure precommitment

## Peasant-Dictator Example

|      | eat   | grow |
|------|-------|------|
| low  | 0*,1  | 1,2* |
| high | 0*,1* | 3*,0 |

| $p(\text{low})$       | BR          | worst in support |
|-----------------------|-------------|------------------|
| 1                     | grow        | 1                |
| $\frac{1}{2} < p < 1$ | grow        | 1                |
| $p = \frac{1}{2}$     | any mixture | $\leq 1$ (low)   |
| $0 < p < \frac{1}{2}$ | eat         | 0                |
| $p = 0$               | eat         | 0                |

check:  $w^1(a^1) = \frac{\bar{v}^1 - (1 - \delta)u^1(a^1, \alpha^2)}{\delta} \geq n^1$

as  $\delta \rightarrow 1$  then  $w^1(a^1) \rightarrow \bar{v}^1 \geq n^1$

*min problem*

fix  $\alpha = (\alpha^1, \alpha^2)$  where  $\alpha^2$  is a b.r. to  $\alpha^1$

$$\underline{v}^1 \geq (1 - \delta)u^1(a^1, \alpha^2) + \delta w^1(a^1)$$

$$\underline{v}^1 \leq w^1(a^1) \leq n^1$$

Biggest  $u^1(a^1, \alpha^1)$  must have smallest  $w^1(a^1) = \underline{v}^1$

$$\underline{v}^1 = (1 - \delta)u^1(a^1, \alpha^2) + \delta \underline{v}^1$$

conclusion

$$\underline{v}^1 = \max u^1(a^1, \alpha^2)$$

or

$$\underline{v}^1 = \min_{\alpha^2 \in BR^2(\alpha^1)} \max u^1(a^1, \alpha^2)$$

that is, constrained minmax

## *Example*

|   | L    | M   | R   |
|---|------|-----|-----|
| U | 0,-3 | 1,2 | 0,3 |
| D | 0,3* | 2,2 | 0,0 |

static Nash gives 0

minmax gives 0

worst payoff in fact is 0

pure precommitment also 0

## *mixed precommitment*

$p$  is probability of up

to get more than 0 must get SR to play M

$$-3p + (1-p)3 \leq 2 \text{ and } 3p \leq 2$$

first one

$$-3p + (1-p)3 \leq 2$$

$$-3p - 3p \leq -1$$

$$p \geq 1/6$$

second one

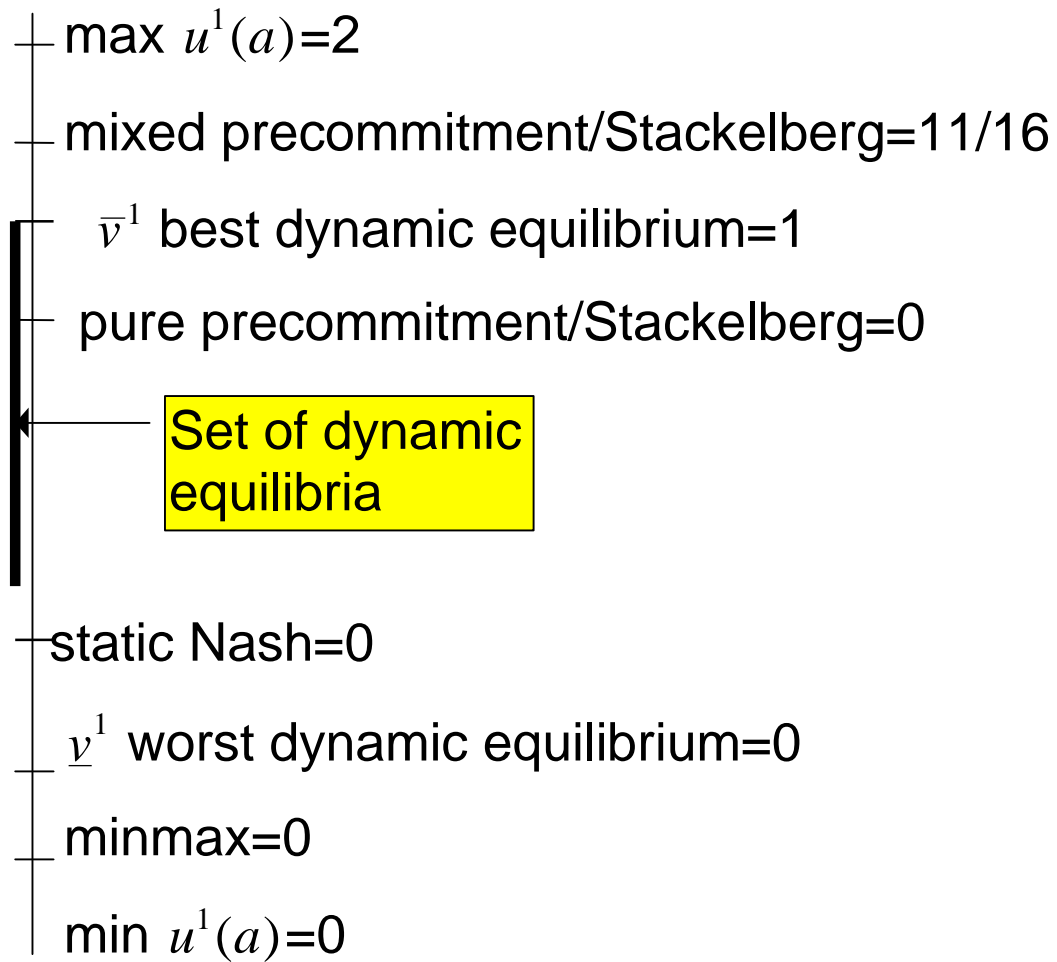

$$3p \leq 2$$

$$p \leq 2/3$$

want to play D so take  $p = 1/6$

$$\text{get } 1/6 + 10/6 = 11/6$$

utility to long-run player

*calculation of best dynamic equilibrium payoff*

$p$  is probability of up

| $p$             | $BR^2$ | worst in support |
|-----------------|--------|------------------|
| $<1/6$          | L      | 0                |
| $1/6 < p < 5/6$ | M      | 1                |
| $p > 5/6$       | R      | 0                |

so best dynamic payoff is 1
